Najah Stage 2

Build the human reference, compare judges, then evaluate the locked test.

Model comparison · critical-case detection

300 human-reference episodes: 26 critical and 274 noncritical. Earlier critical-only experiment—not the new full-rubric evaluation.

Refresh comparison

Configurations actually evaluated

Configuration	API model	Thinking effort	Valid critical-screen outputs
Sonnet 5.5 · Baseline/default	claude-sonnet-5-5	Provider default · 8,000-token cap	300/300
Sonnet 5.5 · Maximum thinking	claude-sonnet-5-5	Maximum · 16,000-token cap	284/300
Opus 5.5 · Medium thinking	claude-opus-5-5	Medium · 16,000-token cap	300/300
Opus 5.5 · Maximum thinking	claude-opus-5-5	Maximum · 16,000-token cap	286/300

There was no default/no-thinking Opus baseline in this comparison. The lower-effort Opus configuration used adaptive medium thinking. Sonnet default is not a claim that the model performs no internal reasoning.

Selection criterion: among configurations with complete results, maximise held-out critical detection while keeping held-out false flags at or below 20%. Do not select from incomplete previews or from same-data fitted curves alone.

Why Sonnet is being used now

Sonnet baseline is the user-selected operational baseline for the full-rubric rollout. It is not the demonstrated accuracy winner. In the completed held-out critical-screen comparison, Opus medium caught 16/26 critical episodes versus Sonnet's 15/26, and falsely flagged 49/274 versus 51/274. The difference is small and needs fresh confirmation.

Baseline avoids the maximum-thinking configurations, which still have invalid critical-screen outputs. This page does not claim a measured cost advantage or automatically change the active model.

Comparison method

- (•) Held-out calibration · target ≤20% false flags
- ( ) Fixed threshold 12 · includes partial previews

We compared four configurations: Sonnet 5.5 with default settings and maximum thinking, and Opus 5.5 with medium and maximum thinking. Our selection criterion was to maximise critical-case detection while keeping false flags among noncritical cases at or below 20%.

Model	Valid / planned	Failed	Pending	Status	Critical caught	Noncritical falsely flagged
Sonnet 5.5 · Baseline/default	300 / 300	0	0	Complete	15 / 26 (57.7%)	51 / 274 (18.6%)
Sonnet 5.5 · Maximum thinking	284 / 300	16	0	Incomplete — not ranked	Unavailable	Unavailable
Opus 5.5 · Medium thinking	300 / 300	0	0	Complete	16 / 26 (61.5%)	49 / 274 (17.9%)
Opus 5.5 · Maximum thinking	286 / 300	14	0	Incomplete — not ranked	Unavailable	Unavailable

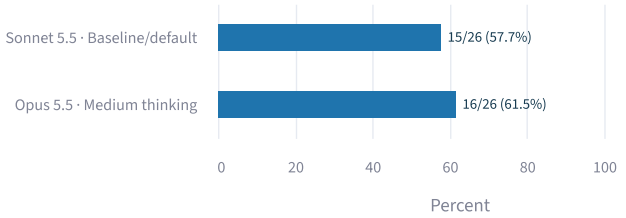

Download comparison table

Critical detection % = caught ÷ human-critical episodes scored. False-flag % = falsely flagged ÷ human-noncritical episodes scored—not a percentage of all flags.

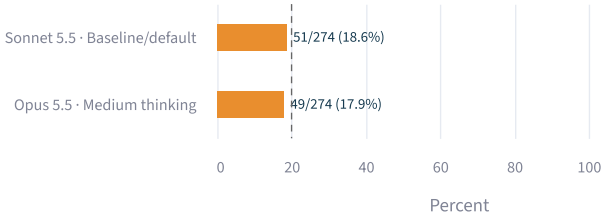

Paired panels · recommended | Tradeoff scatter | Absolute counts

Recommended for presentation: separate panels make the opposite goals clear. Every bar includes count/denominator and percentage. Dashed line = 20% false-flag limit.

Critical cases caught · higher is better

Noncritical falsely flagged · lower is better

Thresholds were selected outside each participant-held-out fold. The 20% training limit is not a guarantee on future data. Incomplete models are absent from plots.

Threshold choice and tradeoffs

Three different numbers must not be confused: the earlier full-dataset critical screen used 12; Sonnet's full-data fitted threshold is 14 at the 20% target; its held-out estimate used fold-specific thresholds of 12 or 14. Threshold 14 is a fitted candidate, not a newly deployed setting.

The full-rubric judge currently supplies Yes/No/Cannot determine for critical failure; these screening probability thresholds do not apply to that new rubric run.

Threshold-analysis model

Sonnet 5.5 · Baseline

Fitted threshold · ≤20% false flags

14

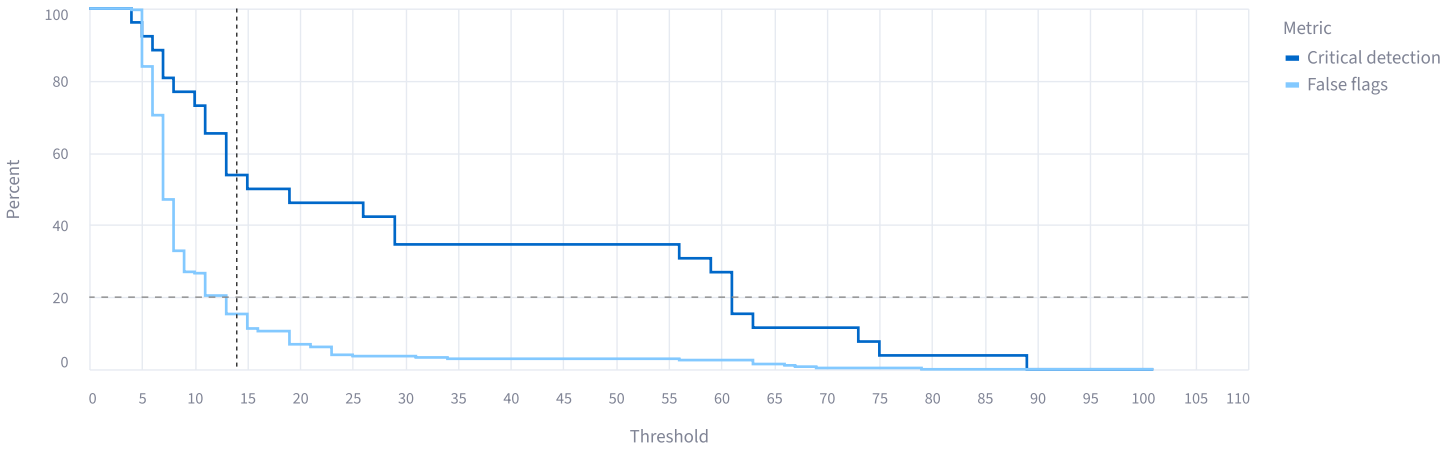

Critical caught · fitted

14 / 26 (53.8%)

Noncritical falsely flagged · fitted

42 / 274 (15.3%)

Selection rule: catch the most critical cases while falsely flagging at most 20% of noncritical cases; break ties by fewer false flags, then a higher threshold.

Horizontal dashed line: 20% false-flag limit. Vertical dotted line: fitted threshold. These curves use all 300 labels for both fitting and evaluation; they are descriptive, not held-out results. 101 flags none. Lower thresholds generally catch more cases but raise more false alarms.
